**Abstract**—The abstract goes here.

## I. INTRODUCTION

Every system is a distributed system nowadays [1].

Python is currently one of the most popular programming languages. At the time of writing this paper<sup>1</sup> Python is the 4th most popular programming language cf. the Tiobe Index<sup>2</sup>.

*Todo: Flask summary goes here*

A search on GitHub with the keyword “language:Python” returns more than 500K open source projects written in the language. If we restrict the search by adding the keyword “Flask” we obtain a listing of 25K projects, that is, 5% of all the Python projects. Flask – advertised as a *micro-framework* – is a lightweight alternative to web site and service development.

However, there is no dedicated solution for monitoring the performance of Flask web-applications. Thus, every one of those Flask projects faces one of the following options when confronted with the need of gathering insight into the runtime behavior of their implemented service:

- 1) Use a heavyweight professional API monitoring setup they usually require setting up a different server and can not take advantage of the already existing
- 2) Implement their own analytics tool
- 3) Live without analytics insight into their services<sup>3</sup>

*Todo: For the first point in the list, we can also argue that analytics solutions like Google Analytics can be used, but they have no notion of versioning/integration with the development lifecycle. Feel free to cite [2] for service evolution purposes*

For projects which are done on a budget (e.g. research projects, startups) the first and the second options are often not available due to time and financial constraints.

<sup>1</sup>June 2017

<sup>2</sup>TIOBE programming community index is a measure of popularity of programming languages, created and maintained by the TIOBE Company based in Eindhoven, the Netherlands

<sup>3</sup>This is very real option: and is exactly what happened to the API that will be presented in this case study for many months.

To avoid these projects ending up in the third situation, in this paper we present a low-effort, lightweight service monitoring API for Flask and Python web-services.

To start using our Python library for service visualization solution one needs to one line of to connect their Flask application object with the dashboard and one extra line of code to import the library:

Listing 1. Configuring the Flask Dashboard is straightforward

```
import dashboard
dashboard.bind(app=flask_app)
```

*ML: Thijs, Patrick: a small description of how the dashboard automatically intercepts the calls to the various API calls*

*ML: Thijs, Patrick: mention also that the dashboard automatically is available at /dashboard endpoint*

*ML: Thijs, Patrick: a small screenshot of how the dashboard allows one to select the interesting*

## II. CASE STUDY

Zeeguu is a platform and an ecosystem of applications for accelerating vocabulary acquisition in a foreign language [3] and is used as a case study for the remainder of this paper where all the figures are captured from the actual deployment of Flask Dashboard in the context of the Zeeguu platform<sup>4</sup>

The architecture of the ecosystem has at its core an API implemented with Flask and Python and a series of satellite applications that together offer three main intertwined features for the learner:

- 1) Reader applications that provide effortless translations for those texts which are too difficult for the readers
- 2) Interactive exercises personally generated based on the preferences and past likes of the learner
- 3) Article recommendations which are at the appropriate level of difficulty for the reader. The difficulty is estimated based on past exercise and reading activity

<sup>4</sup>Within the Flask Dashboard the figures are interactive offering basic data exploration capabilities: filter, zoom, and details on demand[4]

The core API provides correspondingly three types of functionality: contextual translations, article recommendations, and personalized exercise suggestions. The core API of system is a research project, which sustains at the moment of writing this article the reading and practice of about two hundred active beta-tester accounts.

### Structure of the Paper

The remainder of this paper is structured as follows: In Sections III, IV, V we dedicate a separate section to three types of analysis that Flask Dashboard supports and present a the way the visualizations support these types of analysis.

ML: we should consider adding also one section in which the architecture/implementation and main features of the dashboard are presented before going on with discussing them in more depth in the following sections — this should include a rundown on which views are provided from where (overview or per endpoint)

## III. OVERALL ENDPOINT UTILIZATION

The most fundamental insight that a service maintainer needs regards service utilization.

Figure 1 shows a first perspective on endpoint utilization that Flask Dashboard provides: a stacked bar chart of the number of hits to various endpoints grouped by day <sup>5</sup> shows that at its peak the API has about 2500 hits per day. The way users interact with the platform can also be inferred since the endpoints are indicators of different activity types, e.g.:

- 1) `api.get_possible_translations` is an indicator of the amount of reading the users are doing
- 2) `api.report_exercise_outcome` is an indicator of the amount of vocabulary practice the users are doing

Fig. 1. The number of requests per endpoint per day view shows the overall utilization of the monitored application

This visualization also provides feedback to the maintainer when deciding about endpoint deprecation, the most elementary way of *understanding the needs of the downstream* [5]. In our case study, the maintainer decided to not remove several endpoints once they saw that, contrary to their expectations, they were being used.<sup>6</sup>

<sup>5</sup>We recommend obtaining a color version of this paper for better readability

<sup>6</sup>Usage information can also be used to increase the confidence of the maintainer that a given endpoint is not used, although it is not a proof.

A second type of *utilization* question that an API maintainer can answer by using the Flask Dashboard regards cyclic patterns of usage during various times of day.

Fig. 2. Usage patterns become easy to spot in the requests per hour heatmap

Figure 2 shows the users of the Zeeguu API not practicing languages at night, but otherwise hitting the API around the clock with several hundred hits per hour.

## IV. VISUALIZING SERVICE PERFORMANCE

The Flask Dashboard also collects information regarding endpoint performance. The view in Figure 3 summarizes the response times for various endpoints by using box-and-whisker plots.

Fig. 3. The response time (in ms) per monitored endpoint view allows for identifying performance variability and balancing issues

After investigating this view it became clear to the maintainer that three of the endpoints had very large variation in performance. One of the three was most critical was optimized first: the `api.get_possible_translations` is part of a live interaction and it having such variable performance was a usability problem for the users of the reader applications.

To be able to see their improvements in action, the maintainer had to add an extra configuration information to be able to find the '.git' folder from where to retrieve the current version of the deployed application:

Listing 2. Configuring the Flask Dashboard with the path to the .git folder enables the generation of evolutionary performance graphs

```
dashboard.config.git = 'path/to/git-root/of/app'
```

After redeploying the API, the dashboard can now automatically detect the current version of the project, and can group measurements by version. Flask Dashboard can now generate the view in Figure 4 where the performance of the give endpoint is tallied by version.

Fig. 4. Visualizing The Performance Evolution of the `api.get_possible_translations` endpoint

This way the maintainer could confirm that the performance of the translation endpoint improved: in the latest version (bottom-most box plot in Figure 4) the entire box plot moved to the left and there are fewer outliers.

The Flask Dashboard also collects **extra information about outliers**: Python stack trace, CPU load, request parameters, etc. in order to allow the maintainer to investigate the causes of these exceptionally slow response times.

In order to address this, but not degrade the usual performance the Flask Dashboard tracks for every endpoint a running average value. When it detects that a given request is an outlier with respect to this past average running value, it triggers the *outlier data collection routine* which stores all the previously listed extra information about the current execution environment.

## V. USER CENTERED VISUALIZATION

For service endpoints which run computations in real time, the operator of a system must understand the endpoint performance on a per-user basis, especially for situations where

Listing 3. TBA

```
# app specific way of extracting the user
# from a flask request object
def get_user_id(request):
    sid = int(request.args['session'])
    session = User.find_for_session(sid)
    return user_id

# attaching the get_user_id function
dashboard.config.get_group_by = get_user_id
```

the system response time is a function of some individual user load<sup>7</sup>

Flask Dashboard provides a way of grouping information on a per user basis. However, to do this, the developer must specify the way in which a given API call can be associated with a given user. There are multiple ways, the simplest utilizes again the common expectations of Flask applications which offers a global `request` object which contains a `session` object which encapsulates information:

In the Zeeguu case study, one of the slowest endpoints, and one with the highest variability is `api.get_article_difficulties`: it retrieves a list of recommended articles for a given user. However, since a user can be subscribed to anything from one to three dozen article sources, and since the computation of the difficulty is personalized and it is slow, the variability in time among users is likely to be very large.

Figure 5 shows some of the results of calling the `api.get_article_difficulties` endpoint for various users. The figure shows that the response times for this endpoint can vary considerably for different users.

The limitation of the previous view is that it does not present the information also on a per version basis. To address this, a different visual perspective entitled *Performance per User per Version* Figure 6 attempts to present the information If we try to show also per version:

For the situations in which the user information is not available, the Flask Dashboard tracks out of the box information about different IPs. In some cases this might be a sufficiently good approximation of the user diversity and identity.

## VI. DISCUSSION

### A. Integrating with Different Deployment Strategies in Order to Automatically Monitor System Evolution

The main goal of the Flask Dashboard design was to allow analytics to be collected and insight to be gleaned by making the smallest possible changes to the running API. To allow the collection of evolutionary information

This technique assumes that the web server code which is the target of the monitoring is deployed using `git` in the following way:

- 1) The deployment engineer pulls the latest version of the code from the integration server; this will result in a new commit being pointed at by the HEAD pointer than previously
- 2) The deployment engineer restarts the new version of the service. At this point, the Flask Dashboard detects that a new

<sup>7</sup>E.g. in GMail some users have two emails while other have twenty thousand and this induces different response times for different users

Fig. 5. The `api.get_article_difficulties` shows a very high variability across users

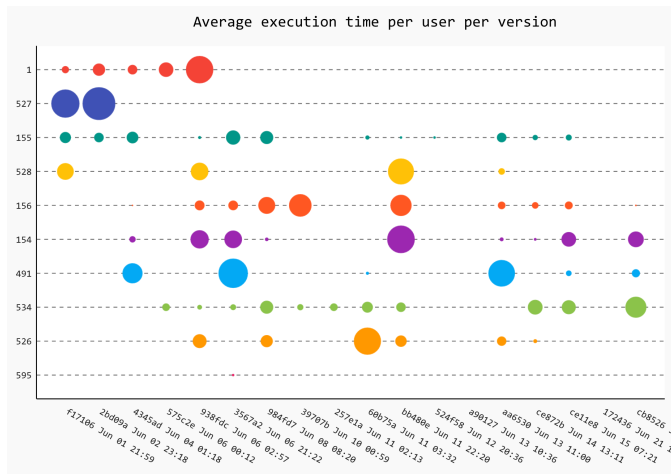

Fig. 6. Caption here

HEAD is present in the local code base and consequently starts associating all the new data points with this new commit<sup>8</sup>

The advantage of this approach is the need for minimal configurability. The disadvantage is that it will consider the smallest of the commits<sup>9</sup> and the shortest lived commits<sup>10</sup>, as a distinct way of grouping the data points.

Another possible extension point here is supporting other version control systems (e.g. Mercurial). However, this is a straightforward extension.

<sup>8</sup>The Flask Dashboard detects the current version of the analyzed system the first time it is attached to the application object, and thus, assumes that the Flask application is restarted when a new version is deployed. This is in tune with the current version of Flask, but if the web server will support dynamic updates in the future, this might have to be taken into account

<sup>9</sup>Even one that modifies a comment

<sup>10</sup>A commit which was active only for a half an hour before a new version with a bug fix was deployed

## B. User-Awareness

User awareness as presented in Section V is useful, but the scalability of the approach must be taken into consideration. In our case study we had about several hundreds users (of which about two hundred were active during the )

## C. Tool and Source Code Availability

Flask Dashboard is implemented for Python 3.6 and is available on the Python Package Index repository<sup>11</sup> from where it can be installed on any system that has Python installed by running `pip install flask_dashboard` from the command line.

The code of Flask Dashboard is published under a permissive MIT license and is available on GitHub.<sup>12</sup>

The images in this paper are screenshots of the interactive visualizations from the deployment of Flask Dashboard in the context of the Zeeguu core API. The actual deployment can be consulted online by the reviewers and readers of this article<sup>13</sup>.
